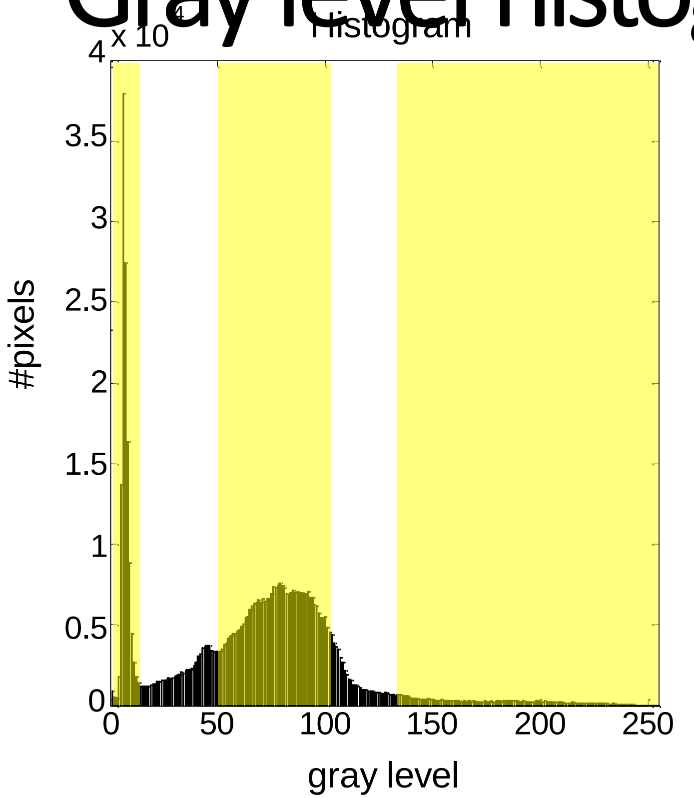
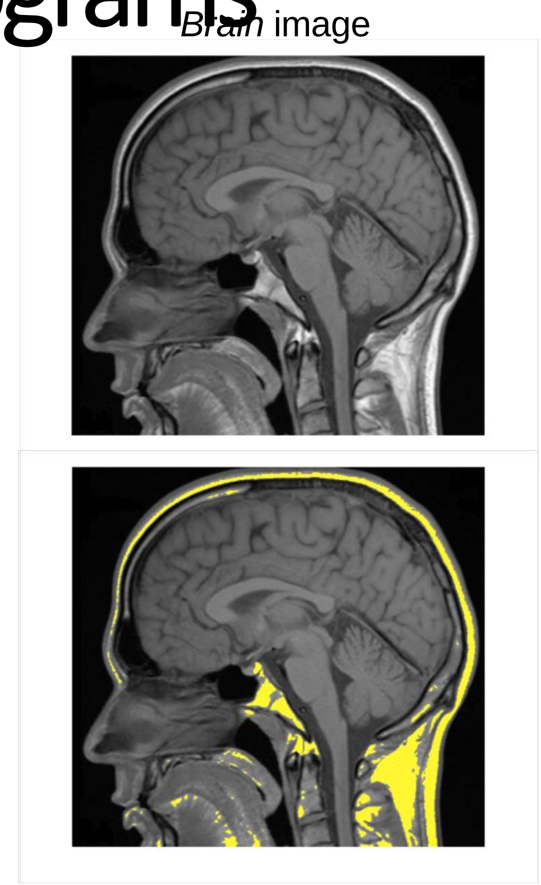
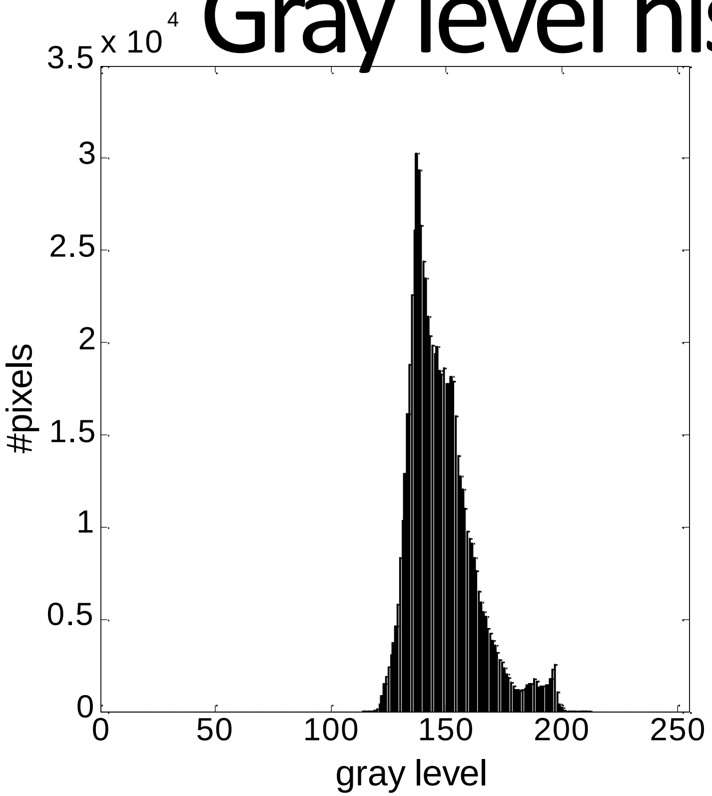
Gray level histograms





Gray level histograms



Bay image

Gray level histogram in viewfinder

Gray level histograms

- To measure a histogram:
  - For B-bit image, initialize 2^B counters with 0
  - Loop over all pixels x,y
  - When encountering gray level $f[x,y]=i$, increment counter $\#\iota$
- Normalized histogram can be thought of as an estimate of the probability distribution of the continuous signal amplitude
- Use fewer, larger bins to trade off amplitude resolution against sample size.

Histogram equalization

Idea:

Find a non-linear transformation

$$\boxed{g = T(f)}$$

that is applied to each pixel of the input image $f[x,y]$, such that a uniform distribution of gray levels results for the output image $g[x,y]$.

Histogram equalization

Analyse ideal, continuous case first ...

Assume

- Normalized input values $0 \le f \le 1$ and output values $0 \le g \le 1$
- $T(f)$ is differentiable, increasing, and invertible, i.e., there exists

$$f = T^{-1}(g) \qquad 0 \le g \le 1$$

Goal: pdf $p_g(g) = 1$ over the entire range $0 \le g \le 1$

Histogram equalization for continuous case

- From basic probability theory

$$p_f(f) \xrightarrow{f} \boxed{T(f)} \xrightarrow{g} \qquad p_g(g) = \left[p_f(f) \frac{df}{dg} \right]_{f=T^{-1}(g)}$$

- Consider the transformation function

$$\boxed{g = T(f) = \int_0^f p_f(\alpha)\, d\alpha \qquad 0 \le f \le 1}$$

- Then . . .

$$\frac{dg}{df} = p_f(f)$$

$$p_g(g) = \left[p_f(f) \frac{df}{dg} \right]_{f=T^{-1}(g)} = \left[p_f(f) \frac{1}{p_f(f)} \right]_{f=T^{-1}(g)} = 1 \qquad 0 \le g \le 1$$

Histogram equalization for discrete case

- Now, f only assumes discrete amplitude values $f_0, f_1,,,, f_{L-1}$ with empirical probabilities

$$P_0 = \frac{n_0}{n} \qquad P_1 = \frac{n_1}{n} \qquad ! \qquad P_{L-1} = \frac{n_{L-1}}{n} \qquad \text{where } n \text{ is total number of pixels}$$

- Discrete approximation of $g = T(f) = \int_0^f p_f(\alpha)\, d\alpha$

$$\boxed{g_k = T\left[f_k\right] = \sum_{i=0}^{k} P_i \qquad \text{for } \; k = 0,1...,L-1}$$

- The resulting values g_k are in the range $[0,1]$ and might have to be scaled and rounded appropriately.

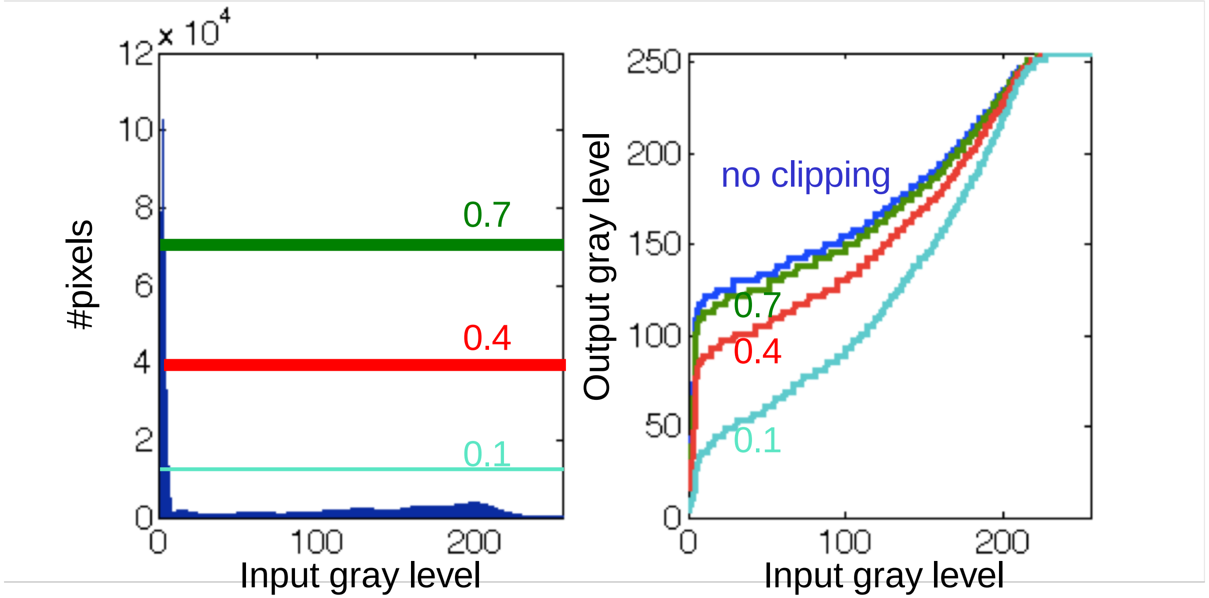
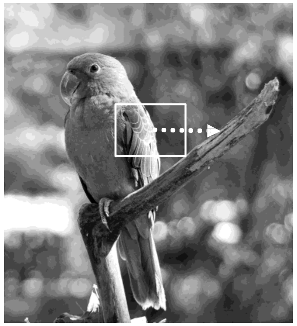
Contrast-limited histogram equalization

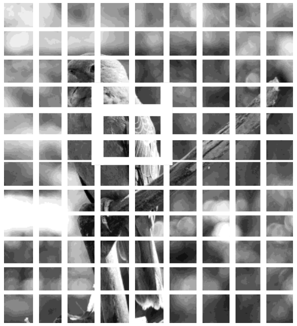


Adaptive histogram equalization

- Histogram equalization based on a histogram obtained from a portion of the image



Sliding window approach:
different histogram (and mapping) for every pixel



Tiling approach:
subdivide into overlapping regions, mitigate blocking effect by smooth blending between neighboring tiles

- Limit contrast expansion in flat regions of the image, e.g., by clipping histogram values.
 ("Contrast-limited adaptive histogram equalization")

[Pizer, Amburn et al. 1987]
